- Responsive Web Design
- Git and GitHub
- VS Code
- Adobe Photoshop, Illustrator, and InDesign
- Python
- SQL and MySQL

Reflection

Print Decisions

Print Decisions For print, I simplified the resume so it works better as a clean PDF instead of a website page. I changed the background to white, changed the text to black, used a print-friendly serif font, and set the size in points. I also hid navigation, buttons, the contact form, and other interactive elements because they do not help on paper. The biggest difference was adding the link URLs after links with `::after`. On screen, a linked URL can stay hidden behind readable link text, but on paper the link would otherwise lose its function. The tradeoff was that surfaced URLs can add visual clutter, but I thought it was worth it so the printed resume still gives useful contact and portfolio information.

Token Audit Results

Token Audit Results When I audited my token files, I looked for custom properties that were declared but not used anywhere else, as well as values that were too similar to justify separate tokens. I did not make major visual changes, but I cleaned up the system by making sure the form and print styles reused existing tokens like color, border, surface, and accent values instead of creating one-off values. The main improvement was consistency. Instead of adding new custom properties for every form spacing, border, or color choice, I reused the existing design system. This made the token files easier to understand because the tokens still feel intentional rather than cluttered with small variations that only apply once.

Form Accessibility

Form Accessibility The contact form uses visible label elements for each form control. Each label has a for attribute that matches the id of its input or textarea, such as for="name" matching id="name". This creates a clear programmatic connection between the text label and the form field. For a screen reader user, each field would be announced with its label, so they would hear what information belongs in each control before typing. The required name, email, and message fields also use the required attribute, which helps communicate that those fields must be completed. The checkbox also has a visible label connected to it, so it is not just announced as an unlabeled checkbox. I checked the markup structure and made sure the form can be understood without relying only on visual placement.
