Reflections

You used custom properties to define a small set of design tokens in your starter stylesheet. Imagine a teammate joins your project six months from now and needs to add a dark mode. Explain how the token structure you set up would help or hinder that effort, and what you would change:

The token structure would help a lot because the main colors are already stored in `:root` instead of being repeated throughout the stylesheet. If a teammate needed to add dark mode, they could change values like `--color-bg`, `--color-text`, and `--color-primary` in one place instead of searching through every CSS rule. That makes the site easier to maintain and less likely to break. However, the current token system is still very small. I would probably add more specific tokens, such as `--color-surface`, `--color-border`, and `--color-muted-text`, so dark mode could handle cards, sections, and smaller text more cleanly.

Look at the starter CSS you added to your Practice Site. Identify one value that is still hard coded (not using a custom property) that probably should be a token. Explain why extracting it would matter in a larger project:

One value that is still hard coded is `line-height: 1.6;` in the `body` rule. I would turn that into a token like `--line-height-body: 1.6;`. In a small site, this does not matter much, but in a larger project, typography consistency becomes really important. If every paragraph, card, and section uses random line-height values, the design can start to feel messy. Making it a token would help keep the reading experience consistent across the whole site.

Browse one professional website you admire and open DevTools. Do they use custom properties? Describe what you found and one thing you would do differently based on what you learned this week:

I looked at Reddit because it is a site I use on occasion, and it has a lot of different UI pieces like posts, buttons, sidebars, and comment sections. In DevTools, I noticed that Reddit does use CSS custom properties for parts of its design system, especially for colors and theme-related styling. That makes sense because Reddit has to support a lot of repeated components across many pages. One thing I would do differently based on what I learned is name my tokens more clearly as my site grows, so instead of only having basic names like `--color-bg`, I could add more specific ones like `--color-card-bg` or `--color-border`. That would make future changes easier and more organized.
